

**Example from midterm:** The 20 X 20-in square plate weighs 56 lb and is supported by three vertical wires as shown in the figure to the right.

(a) Determine the tension in each wire.

**Solution:**

The center of mass for the application of  $W$  is at the center of the plate.

Equilibrium of moments around  $z$  axis passing through  $B$  and  $C$

$$\sum M_{Bz} = 0 = W * 6 \text{ in} - T_A * 16 \text{ in} \Rightarrow T_A = \frac{56 \text{ lb} * 6 \text{ in}}{16 \text{ in}} = 21 \text{ lb}$$

Because of symmetry,  $T_C = T_B = T$ .

Equilibrium of forces in the  $y$  direction:

$$\sum F_y = 0 = 2T + T_A - W \Rightarrow T = \frac{56 \text{ lb} - 21 \text{ lb}}{2} = 17.5 \text{ lb}$$

**Answer:**

$$T_A = 21 \text{ lb}$$

$$T_B = T_C = 17.5 \text{ lb}$$

- (b) If a vertical force of 10 lb is applied down on the plate, what is the point of application if it results in all tensions being equal? What is the corresponding tension?

**Solution:**

Now,  $W_b = 10 \text{ lb}$  is applied to the plate at a point  $(x_b, z_b)$ .

Since all the tensions are equal, from an equilibrium of forces in the y direction:

$$\sum F_y = 0 = 3T - W - W_b \Rightarrow T = \frac{56 \text{ lb} + 10 \text{ lb}}{3} = 22 \text{ lb}$$

From symmetry, to maintain an equilibrium of moments around the x axis that passes through A, and because  $T_B = T_C$ , it follows that  $z_b = 10 \text{ in}$ .

To calculate the  $x_b$  consider equilibrium of moments around the z axis passing through B.

$$\sum M_{Bz} = 0 = W_b * (16 \text{ in} - x_b) + W * 6 \text{ in} - T * 16 \text{ in}$$

$$(16 \text{ in} - x_b) = \frac{22 \text{ lb} * 16 \text{ in} - 56 \text{ lb} * 6 \text{ in}}{10 \text{ lb}} = 1.6 \text{ in}$$

$$x_b = 16 \text{ in} - 1.6 \text{ in} = 14.4 \text{ in}$$

- (c) (5 points) What is the maximum distance ( $d$ ) from the z axis for a 150 lb force down to be applied on the plate without the plate tipping?

**Solution:**

For a plate to tip means in this case to start rotating around the BC axis. The extreme case, just before tipping means that  $T_A = 0$ . From equilibrium of moments around BC gives us:

$$\sum M_{BC} = 0 = W * 6 \text{ in} - W_b * (d - 16) \text{ in} \Rightarrow d = \frac{(56 \text{ lb} * 6 \text{ in})}{150 \text{ lb}} + 16 \text{ in} = 18.24 \text{ in}$$

(d) **Bonus** Show on a sketch the area of the plate over which the force in part (c) can act without the plate tipping. Mark relevant distances.

**Solution:**

The plate can tip around one of the three axes  $BC$ ,  $AB$  and  $AC$ . In each of the extreme cases, just before tipping, the tension in the corresponding third cable is zero. In the previous part we calculate the distance  $d$  for the case of tipping around the  $BC$  axis.

The area that the force can be applied to without tipping the plate is marked in gray in the top view of the plate:

$$\tan \alpha = \frac{10}{16} \Rightarrow \alpha = 32^\circ$$

$$d'' = 10 \text{ in} * \sin \alpha = 5.3 \text{ in}$$

$$\sum M_{AB} = 0 = W_b * d' - W * d''$$

$$d' = \frac{W * d''}{W_b} = \frac{56 \text{ lb} * 5.3 \text{ in}}{150 \text{ lb}} = 1.98 \text{ in}$$

$$(16 - x') = \frac{d'}{\sin \alpha} \Rightarrow x' = 16 \text{ in} - \frac{d'}{\sin \alpha} = 12.27 \text{ in}$$

$$z' = x' * \tan \alpha = 7.67 \text{ in}$$

$$20 - z' = 12.33 \text{ in}$$
